Alex Wodak, MD

IN MEMORIAM
Kathleen Coughlin (2015-2019)
John Galea (2013-2018)
Herman Joseph, PhD (2002-2015)
Elizabeth Khuri, MD (2002-2017)
Dan McGill (2007-2022)
Robert Newman, MD (2002-2018)
Beny Primm, MD (2002-2015)
Barry Stimmel, MD (2002-2015)

STOP STIGMA NOW is an independent 501-c3 non-profit organization

LONG-ACTING INJECTABLE NALTREXONE IS A SECOND-LINE TREATMENT FOR MOST INDIVIDUALS WITH OPIOID USE DISORDER

3-23-2022

It is the position of Stop Stigma Now (www.StopStigmaNow.org) and Doctors For America (https://doctorsforamerica.org) that behavioral health agencies and medical providers should . . .

- Communicate to anyone considering pharmacological treatment for opioid use disorder (OUD) that, based on currently available information, long-acting injectable naltrexone (INTX) should be considered as a second-line treatment option for most individuals with moderate or severe OUD,
- and that methadone, buprenorphine and buprenorphine/naloxone, collectively known as opioid agonist therapy (OAT), should be considered as first-line treatments for most such individuals.
- It should also be communicated that individuals should be informed of all FDA-approved options for pharmacologic therapy, and should be able to choose among them in consultation with their healthcare provider,
- and that any approved pharmacologic therapy may be recommended preferentially for OUD of any severity based on individual circumstances.

This position is based on the fact that, unlike OAT, injectable naltrexone has not been clearly demonstrated to reduce fatal overdose deaths, (1 - 6) and has been associated with lower retention in treatment compared with OAT in some studies. (7) (8)

This position is consistent with the published statements reproduced below. The 2019 World Health Organization Model List of Essential Medicines designated methadone and buprenorphine, but not naltrexone, as “essential medicines.” (9)

According to the Clinical Guidelines Program on the Treatment of Opioid Use Disorder by the New York State Department of Health AIDS Institute, updated January 2021, “Clinicians should recommend co-formulated
buprenorphine/naloxone or methadone as preferred treatments for individuals with opioid use disorder... Clinicians should offer extended-release naltrexone to patients who prefer naltrexone for treatment or who are not able to access treatment with or reach their treatment goals with methadone or buprenorphine/naloxone.” (10)

The American Society of Addiction Medicine (ASAM) National Practice Guidelines for the Treatment of Opioid Use Disorder 2020 Focused Update does not describe any FDA approved medications for OUD as more or less effective than any other. (11) However, ASAM’s Policy Statement on Treatment of Opioid Use Disorder in Correctional Settings states that “For individuals who do not want to be treated with methadone or buprenorphine, extended-release injectable naltrexone is an alternative option for relapse prevention during detainment and after release.” (12)

OAT has been described in recent peer-reviewed reports as the “gold standard” or most effective treatment for OUD, or that INTX is appropriate for those who are unable to, or choose not to, use OAT. (13 – 23)

The Food and Drug Administration (FDA) Prescribing Information for Vivitrol, the brand name of XR-NXT, notes that “... Any attempt by a patient to overcome the antagonism by taking opioids is especially dangerous and may lead to life-threatening opioid intoxication or fatal overdose. Patients should be told of the serious consequences of trying to overcome the opioid blockade.” (24)  The Risk Evaluation and Mitigation Strategy (REMS) for Vivitrol required by the FDA states that “Using large amounts of opioids, such as prescription pain pills or heroin, to overcome effects of Vivitrol, can lead to serious injury, coma, and death.” (25)  In December 2019 the FDA issued a warning letter to the manufacturer of Vivitrol for not including serious risks in marketing materials. (26)

A National Academies of Sciences, Engineering, and Medicine 2019 report on medications for opioid use disorder stated that “Emerging evidence suggests that patients can experience an increased risk of overdose when they approach the end of the 28-day period of the extended-release formulation” of INTX. (27)

Some authors have noted that the question of a possible increase in overdose rates associated with the use of INTX has not been settled. (28) (29)  In a commentary (30) on the largest of the two randomized trials to date comparing INTX with buprenorphine-naloxone, (31) it was noted that "total overdoses, fatal and non-fatal, did not differ between groups, but the numbers were noteworthy - 18 for INTX versus 10 for buprenorphine-naloxone. Considering that the
study was not powered to detect overdose differences, there should be continued evaluation of how failure to complete opioid detoxification and induction onto INTX might increase overdose risk."

Nevertheless, INTX is an important option that may be preferred by some, or more appropriate than OAT for particular individuals.

This statement applies to long-acting injectable naltrexone (INTX), and not to implantable naltrexone which has been associated with a reduction in mortality. (32)

For the reasons noted, injectable naltrexone is currently a second line OUD treatment option, after OAT, for most but not all individuals seeking treatment for moderate or severe OUD.

1. Wakeman SE, et al. Comparative Effectiveness of Different Treatment Pathways for Opioid Use Disorder JAMA Netw Open. 2020;3(2). free: https://jamanetwork.com/journals/jamanetworkopen/fullarticle/2760032 ("Our finding that MOUD [Medication for Opioid Use Disorder] treatment with naltrexone was not protective against overdose or serious opioid-related acute care use is consistent with other studies that found naltrexone to be less effective than MOUD treatment with buprenorphine."). [Note that the use of either the oral and/or the injectable naltrexone formulation, XR-NTX, was not identified in this study; XR-NTX was approved in the U.S. for OUD in 2010; this study evaluated claims data between October 3, 2014, to December 31, 2017.]

2. Morgan JR, et al. Overdose following initiation of naltrexone and buprenorphine medication treatment for opioid use disorder in a United States commercially insured cohort. Drug Alcohol Depend. 2019 Jul 1;200:34-39. free: https://www.sciencedirect.com/science/article/pii/S0376871619301310?via%3Dihub ("Among commercially-insured patients who initiate medications for opioid use disorder, buprenorphine, but not naltrexone, was associated with lower risk of overdose during active treatment compared to post-discontinuation."). [Note that treatment with XR-NTX and oral naltrexone were each found to be associated with significantly higher overdose rates compared to buprenorphine, whether on treatment or after recently discontinuing treatment.
https://www.acpjournals.org/doi/abs/10.7326/m17-3107
(“Compared with no MOUD, methadone was associated with decreased all-cause mortality (adjusted hazard ratio [AHR] 0.47 [CI, 0.32 to 0.71]) and opioid-related mortality (AHR 0.41 [CI, 0.24 to 0.70]). Buprenorphine was associated with decreased all-cause mortality (AHR 0.63 [CI, 0.46 to 0.87]) and opioid-related mortality (AHR 0.62 [CI, 0.41 to 0.92]). No associations between naltrexone and all-cause mortality (AHR 1.44 [CI, 0.84 to 2.46]) or opioid-related mortality (AHR 1.42 [CI, 0.73 to 2.79]) were identified.”). [Note that in this study patients treated with both XR-NTX and oral naltrexone were included and were not separately analyzed. Also, there were fewer patients treated for a shorter duration with naltrexone (1099 persons treated for a median of 1 month) vs. buprenorphine or methadone (3022 patients treated with buprenorphine for a median of 4 months, and 2040 patients treated with methadone for a median of 5 months, respectively)].

(One conclusion is that naltrexone reduces mortality. Two naltrexone studies were reviewed: one of oral naltrexone, and one of implantable naltrexone; none with injectable naltrexone).

(Reanalyzed data in Lee JD et al (31), including probable & possible overdoses, and using a time-to-event analysis. A near-significant increased association with overdose of about two-fold was found in the INTX group compared to the buprenorphine-nx group. (HR: 2.10; 95% CI: 0.86, 5.14). During the treatment (i.e. maintenance) phase the risk of overdose was 3.81 (CI: 1.01, 14.36) times higher in the INTX group compared to the buprenorphine-nx group in a Per Protocol analysis).
